Since last SCRUM, I have moved from studying the database structure to preparing the data which our pages need. According to the Page-to-Table mapping in my previous report, my personal contribution in this sprint (branch feature/database-data) is the data and configuration which let the team run the database in local.

I prepared the product seed data (products.json) which is used to populate the product list, and also a docker-compose.yml which runs the NocoDB server in a container. What is more important, I made sure that the actual database file is not committed to the repository — this follows both the assignment requirement ("do not include the database") and also my plan to keep the original database structure unchanged; we only add the seed data and configuration around it.

I opened a pull request and it was merged into main, and I also checked that the seed-data fields can match what the frontend and backend expect, so that the product pages can read the correct data.

This part is labelled as in progress. In next sprint, I will do the documentation of the full Page-to-Table mapping inside the repository, help to connect the remaining pages (cart, account, profile, admin) to their correct tables, and verify the data flow during the integration testing.
